

Idea

Problems

- Find a set of Topt that fits any of the models.
 - What do we vary? $\begin{matrix} \text{species} \\ \text{medium} \end{matrix}$
 - How many points? ($> \neq$ parameters)
 - Maybe use simpler models. (niches of reactions?)
- Literature for more models for Topt?
- Benefits of doing this in a hierarchical way?
 - Easily measure macroscopic properties
 - hope that errors are propagated nicely (final outcome was a reasonably low uncertainty)
 - Philosophical points of view, that everything can be reduced to first principles
 - Impossibility of Bortolotti model to be mechanistic, since it is not a function of the local traits.
